1 Simple Protocol

This document describes the serial protocol of TWN4.

In order to operate this protocol, a firmware type TWN4_Cxvvv_PRSwww.bix is required, where vvv and www are the version numbers.

A firmware as mentioned above combines virtual USB (CDC) or true serial communication with an TWN4 app, which implements the simple protocol (PRS = PRotocol Simple).

This protocol is called simple because it is based on a communication with ASCII characters which can also be tested manually by using a terminal program. There is no additional overhead for things like packet repetition, address bytes...

The simple protocol is also available in binary mode. This means, that the data is not transmitted via ASCII characters but as single bytes.

Moreover it is possible to add a CRC at the end of every transmission. This lets you detect transmission errors.

The communication is based on a command/response structure: TWN4 will only send data to the host as a response of a command. Command and response are lines of bytes terminated by a carriage return. Carriage return is not shown explicitly anymore in the following documentation. A byte is always represented and transmitted by two hexadecimal ASCII characters.

1.1 Command

A command always starts with two bytes which reflect the API and function number to be executed.

1.2 Response

A response always starts with a byte, which reflects execution of the command on protocol level. Following possible error values:

ERR_NONE	0
ERR_UNKNOWN_FUNCTION	1
ERR_MISSING_PARAMETER	2
ERR_UNUSED_PARAMETERS	3
ERR_INVALID_FUNCTION	4
ERR_PARSER	5

1.3 Data Transmission

Data can be transmitted in two ways:

- by sending ASCII characters
- by sending binary values

1.3.1 ASCII

To transmit a value of e.g. 0x1F, it is necessary to split this into two ASCII characters '1' and 'F'. These characters has to be sent sequentially.

1.3.2 Binary

To transmit a value of e.g. 0x1F, it can be sent directly in binary format.

1.3.3 CRC

On both ASCII and binary format, a CRC can be added at the end of each transmission. The CRC is calculated as follows:

```
uint16_t UpdateCRC(uint16_t CRC, byte Byte)
{
    // Update CCITT CRC (reverse polynom 0x8408)
    Byte ^= (byte)CRC;
    Byte ^= (byte)(Byte << 4);
    return (uint16_t)(((Byte << 8) | (CRC >> 8)) ^ (Byte >> 4) ^ (Byte << 3));
}
```

The CRC calculation starts with CRC = 0xFFFF

1.3.4 Reference messages

The following table shows reference messages for function GetUSBType

Mode	CRC	Command (Host -> TWN4)	Response (TWN4 -> Host)
ASCII	Off	"0005\r"	"0001\r"
	On	"000515A7\r"	"000131E1\r"
Binary	Off	0x02 0x00 0x00 0x05	0x02 0x00 0x00 0x01
	On	0x04 0x00 0x00 0x05 0x15 0xA7	0x04 0x00 0x00 0x01 0x31 0xE1

1.4 Data Types

The description of the commands is using data types, which have to be built-up as follows:

Data Type	Description
[Byte]:	One single byte (sent as two hex digits)
[UInt16]:	Two bytes (LSB first)
[UInt32]:	Four bytes (LSB first)
[Bool]:	One single byte which can hold two values: 0 or 1
[Byte Array(n)]:	A sequence of bytes with known and fixed number of bytes. The number of bytes is not transferred explicitly, because both host and TWN4 do know this number.
[Byte Array(Var)]:	A sequence of bytes, where the first byte holds the number of following bytes
[Byte Array(Var), x LB]:	A sequence of bytes, where the first x bytes hold the number of following bytes
[ASCII string]:	A sequence of bytes which contain ASCII characters, except the first byte which holds the number of following bytes

In Simple Protocol, all numbers are sent with LSB first. For example, the number 0x1234 has to be sent as 3412.
